# Recent advances in critical element detection problems 

Ashwin Arulselvan

## Department of Management Science University of Strathclyde

Workshop on Clustering and Search techniques for large scale networks

Oct 25, 2015

## Outline

- Various definitions in the literature
- Three definitions of recent interest
- What has happened so far?
- Where are we going?

## Traditional graph theory problems

Steiner Tree

Dominating sets

Vertex cover

Independent Sets

Cuts

## Generalisation of these ideas

- Multicuts and multiway cuts
- Feedback vertex/edge cover
- Centrality
- Prestige
- Prominence
- k-plex, quasi-cliques
- clique cover, path cover

## Generalisation of these ideas

- Nodes (edges) on deletion that causes fragmentation
- Set of nodes (edges) on inclusion induces a dense subgraph

One such generalisation

- pairwise connectivity of the remaining nodes (deletion - ISP)
- size of the largest connected component (deletion - VC)
- densest induced subgraph (inclusion - Clique)

## Applications

- Jamming/suppressing communication on a network
- Reduce transmissibility of virus and contagion of epidemic
- Drug design
- Emergency response - shelter location
- Coalitions in social networks
- Influential individuals in social networks

## Problem Definition

- Decision Version: K - CNP
- Input: Undirected graph $G=(V, E)$ and integers $k$
- Output: Find a subset $A \subset V$ of $k$ nodes, whose deletion results in maximum pairwise disconnectivity

## Objective function motivation

## Lemma

Let $M$ be a partition of $G=(V, E)$ in to $L$ components obtained by deleting a set $D$ of nodes, where $|D|=k$. Then the objective function $\sum_{h \in M} \frac{\left(\sigma_{h}\left(\sigma_{h}-1\right)\right)}{2} \geq \frac{(|V|-k)^{2}}{2(L-1)}$, with equality holding if and only if $\sigma_{h}=\sigma_{l}, \forall h, l \in M$, where $\sigma_{h}$ is the size of $h^{\text {th }}$ component. of $M$.

## Lemma

Let $M_{1}$ and $M_{2}$ be two sets of partitions obtained by deleting $D_{1}$ and $D_{2}$ sets of nodes, respectively, from graph $G=(V, E)$, where $\left|D_{1}\right|=\left|D_{2}\right|=k$. Let $L_{1}$ and $L_{2}$ be the number components in $M_{1}$ and $M_{2}$, respectively, and $L_{1} \geq L_{2}$. If $\sigma_{h}=\sigma_{l}, \forall h, l \in M_{1}$, then we obtain a better objective function value by deleting the set $D 1$.

## NP-Completeness

k-vertex cover

$(|V|-k)$-Independent set

A reduction from $k$-VCP (Vertex cover problem) or ( $|V|-k$ )-ISP (independent set problem)

## Approximation hardness (rough idea)

An algorithm is $\alpha$-approximate if it terminates with a solution with a value $\leq \alpha O P T$.
$A$ is a NP- hard decision problem and $A \leq_{P} B$ such that
Yes: With value at most a
No: With value at least $b$
We cannot have $\frac{b}{a}$ approximation algorithm for problem $B$

## Approximation hopes for CNP

- ISP (YES instance) 0
- ISP (NO instance) $\geq 1$

UNLIKELY! (Planar graphs, degree bounded graphs)
Positive result
Polynomially solvable in bounded treewidths with unit weights
Di Summa et al. (2013)

## Fixed parameter tractability

- Given a parameter $k$ as an input and size of the input is $n$
- Is there an algorithm to an NP-complete problem that runs in $f(k) O\left(n^{c}\right)$, where $f(k)$ is a function (possibly exponential) in k.

## What about CNP?

Negative on this end too! Through a reduction from clique cover problem
Hermelin et. al. (2015)

## Formulation

$\min \sum_{i, j \in V} u_{i j}$
s.t.

$$
\begin{aligned}
& u_{i j}+v_{i}+v_{j} \geq 1, \forall(i, j) \in E, \\
& u_{i j}+u_{j k}-u_{k i} \leq 1, \forall(i, j, k) \in V, \\
& u_{i j}-u_{j k}+u_{k i} \leq 1, \forall(i, j, k) \in V, \\
& -u_{i j}+u_{j k}+u_{k i} \leq 1, \forall(i, j, k) \in V, \\
& \sum_{i \in V} v_{i} \leq k, \\
& u_{i j} \in\{0,1\}, \forall i, j \in V, \\
& v_{i} \in\{0,1\}, \forall i \in V .
\end{aligned}
$$

## Heuristics

- Find a maximal independent set (MIS)
- Add as many vertices as possible "greedily" to the independent set
- Improve it with Local search
- Repeat the trials with different starting MIS and pick the best one

## Results - Network Data from Krebs

Heuristic found optimal solution in all cases in 0.02 s on an average!

## Krebs' terrorist network

## Krebs' terrorist network

## Results - Randomly Generated Sparse Graphs

- Optimal solution found for each instance
- Average CPLEX time: 289.44 seconds
- Average Heuristic time: 0.33 seconds

## What happened since 2009?

1. On new approaches of assessing Network vulnerability: Approximation and hardness, Xuan, Thai, Pardalos, ACM, 2011
2. Robust optimizaztion of graph partitioning and critical node detection, Fan, Pardalos, COA, 2010
3. Complexity of critical node detection problem in trees Di Summa et. al., C\&OR, 2011
4. Multicriteria optimization model for humanitarian aid distribution, Vitoriano et. al, JOGO,2011
5. Evaluation of strategies to mitigate contagion spread using social network characteristics, Ventresca, Aleman, SN, 2013
6. Polynomial aglroithms for solving a class of critical node problems in trees and SP-graphs, Shen, Smith, Networks, 2012
7. Identifying critical nodes in PPI networks, Boginski, Commander, 2009
8. Economic analysis of N-k power grid contingenccy selection by interdiction methods, Fan, Xu, Pardalos, ES, 2011.
9. ...

## Where are we headed?

CNP is as hopeless as ISP (from a worst case perspective) Independent set problem

- ISP average case scenarios are tested
- A random graph $G(n, m)$, for $m=\frac{1}{2}\binom{n}{2}$, $\alpha(G(n, m)) \sim 2 \log _{2}(n)(1+o(1))$ whp (tends to 1 as $\left.n \rightarrow \infty\right)$.
- A greedy inclusion maximal independent set is of size $\log _{2} n$, whp. Grimmett and McDiarmid, 1975 (Still open: An $(1+\epsilon) \log n$-algorithm)
- For $d=\frac{2 m}{n},\left(2-\epsilon_{d}\right) n \frac{\ln d}{d} \leq \alpha(G(n, m)) \leq\left(2+\epsilon_{d}\right) n \frac{\ln d}{d}$ (with $\epsilon_{d} \rightarrow 0$ in the limit of large $d$ )

## Cardinality Critical Node Problem (CCNP)

- Alternate Formulation:
- Suppose now, we want to limit the connectivity of the nodes.
- We can impose a constraint for this.
- Now, we minimize the number of nodes deleted to satisfy this constraint.
- We have the CARDINALITY CONSTRAINED CRITICAL NODE PROBLEM
- The property is hereditary and non-trivial (Yanakakis and Lund, 1999)
- The problem is NP-hard and Max-SNP hard

## CCNP - Heuristics

- We modified the MIS heuristic for this problem, but it is easy to create pathological instances.
- We also implemented a Genetic Algorithm for the CC-CNP.
- The GA was able to find optimal solutions for all instances tested.
- Example (again). Here $L=4$. Opt Soln $=17$.

## Results - Network Data

## Formulation

$\min \quad \sum_{i \in V} v_{i}$
s.t.

$$
\begin{aligned}
& u_{i j}+v_{i}+v_{j} \geq 1, \forall(i, j) \in E, \\
& u_{i j}+u_{j k}-u_{k i} \leq 1, \forall(i, j, k) \in V, \\
& u_{i j}-u_{j k}+u_{k i} \leq 1, \forall(i, j, k) \in V, \\
& -u_{i j}+u_{j k}+u_{k i} \leq 1, \forall(i, j, k) \in V, \\
& \sum_{i \in V} u_{i j} \leq L, \forall j \in V \\
& u_{i j} \in\{0,1\}, \forall i, j \in V, \\
& v_{i} \in\{0,1\}, \forall i \in V .
\end{aligned}
$$

## We have a better formulation!

$$
\begin{aligned}
& \min \sum_{i \in V} x_{i} \\
& \sum_{i \in S} x_{i} \geq 1, \quad \forall S \subset V,|S|=L+1, G[S] \text { is connected } \\
& \quad \mathbf{x} \in\{0,1\}^{|V|}
\end{aligned}
$$

Set cover formulation
We can get best $(O(L), O(\log n))$-approximation using the LP relaxation

Hardness of approximation

- We can't do better than 2-approximation (from vertex cover)
- Open problem: Close this gap!

Also open: Fixed parameter tractability. Can we have an algorithm that runs in $f(k, L) O\left(n^{c}\right)$ ?

## Densest k- subgraph

## Problem definition

Input: Given a graph $G(V, E)$ and an integer $k$
Output: Find a set of $k$ nodes, which induces the densest subgraph (number of edges is maximised).

- The problem is NP-hard (even when the maximum degree is $\leq 3$ )
- It is APX-hard in general
- Best known approximation in the general case is $O(n)$

Bounded degree graphs (degree $\leq d$ )

- APX-hard assuming the SSE conjecture is true
- $\left(1-e^{\frac{1}{d}}\right)$-approximation is possible $\left(\approx \frac{1}{d}\right)$

## Graph expansion

Given $d$-regular graph $G(V, E)$, expansion of a subset $S \subset V$ is

$$
\Phi_{G}(S)=\frac{|E(S, V \backslash S)|}{d|S|}
$$

Expansion of the graph with respect to $\delta>0$ :

$$
\Phi_{G}(\delta)=\min _{|S|=\delta|V|} \Phi_{G}(S)
$$

## SSE Conjecture

Definition (Gap-SSE $(\eta, \delta)$ )
Given a d-regular graph $G(V, E)$ and constants $\eta, \delta>0$ distinguish whether:

$$
\text { Yes : } \Phi_{G}(\delta) \leq \eta
$$

No: $\Phi_{G}(\delta) \geq 1-\eta$
The SSE conjecture is stated as follows:
Conjecture
For every $\eta>0$, there exist a $\delta$ such that $\operatorname{Gap-SSE}(\eta, \delta)$ problem is NP-hard.
[Raghavendra, Steurer, 2010]

## APX-hard

- Intermediate problem: Find a node set $S$ of size $k$ that has the maximum value for $\frac{2|E(S)|}{d k}$
- "Same" as the DkS problem.
- Define the term $\bar{\Phi}_{G}(\delta)=1-\Phi_{G}(\delta)$
- This would distinguish instances

$$
\begin{aligned}
& \text { Yes: } \bar{\Phi}_{G}(\delta) \geq 1-\eta \text { and } \\
& \text { No: } \bar{\Phi}_{G}(\delta) \leq \eta \text {. }
\end{aligned}
$$

Assuming that the SSE conjecture is true, this would yield a contradiction.

## Greedy algorithm

Works with weights on nodes $w: V \rightarrow \mathbb{R}_{+}$and profits on edges $p: E \rightarrow \mathbb{R}_{+}$. It also works on hypergraphs (with edges correspond to multiple nodes)

- Create new weights $w_{i}^{\prime}=\frac{w_{i}}{d_{i}}$ for all nodes
- Arrange edges by profit to weight ratio $\frac{p_{i, j}}{\left(w_{i}^{\prime}+w_{j}^{\prime}\right)}$
- Enumerate all edge sets of size $\leq 2$,
- Augment the set with edges in the above order (until budget $B$ is not violated)
[Wolsey, 82], [Sviridenko, 03], [Khuller, Moss and Naor, 99]

## A weak algorithm

$$
\begin{aligned}
& \mathcal{P}_{1}: \max \sum_{i=1}^{m} w_{i} x_{i} \\
& \sum_{j=1}^{n} y_{j} \leq K \\
& y_{j} \geq x_{i}, \forall(i, j) \in E \\
& \mathbf{y} \in\{0,1\}^{|V|} \\
& \mathbf{x} \in\{0,1\}^{|E|}
\end{aligned}
$$

- Every integral feasible solution to $\mathcal{P}_{2}$ is feasible to feasible to $\mathcal{P}_{1}$.
- Every feasible solution to $\mathcal{P}_{1}$ scaled down by $d$ is feasible to $\mathcal{P}_{1}$
- Solve $\mathcal{P}_{2}$ to get a $\frac{1}{d+\epsilon}$-approximation for $\mathcal{P}_{1}$

## Tighter Analysis of greedy

Let $Y$ be the first two items we pick in our solution. Now consider the items in OPT and by the greedy algorithm $1, \ldots \ell, \ell+1$. We define $\widehat{W}$ as follows:

$$
\widehat{W}=\sum_{e=1}^{\ell+1} W_{e}^{\prime}=\sum_{e=1}^{\ell+1} \sum_{i \in S_{e}} \frac{w_{i}}{d_{i}}
$$

Multiplying by $d$ throughout, we get

$$
d \widehat{W}=\sum_{e=1}^{\ell+1} d W_{i}^{\prime}=\sum_{e=1}^{\ell+1} \sum_{i \in S_{e}} d \frac{w_{i}}{d_{i}} \geq \sum_{i=1}^{\ell+1} \sum_{i \in S_{e}} w_{i} \geq W\left(\bigcup_{e=1}^{\ell+1} S_{e}\right) \geq B
$$

## Tighter Analysis

$$
\begin{aligned}
\sum_{j=1}^{\ell+1} p_{i} & \geq\left(1-\prod_{j=1}^{\ell+1}\left(1-\frac{W_{j}^{\prime}}{B}\right)\right) P(O P T \backslash Y) \\
& \geq\left(1-\prod_{j=1}^{\ell+1}\left(1-\frac{W_{j}^{\prime}}{d \widehat{W}}\right)\right) P(O P T \backslash Y) \\
& \geq\left(1-\left(1-\frac{1}{d(\ell+1)}\right)^{\ell+1}\right) P(O P T \backslash Y) \\
& \geq\left(1-e^{-\frac{1}{d}}\right) P(O P T \backslash Y) .
\end{aligned}
$$

Our solution $=P(Y)+\sum_{j=1}^{\ell} p_{i}$

## Summary

- K-CNP
- Integer linear programming
- Complexity issues
- Bicriteria results?
- Algorithm for massive graphs?
- CC-CNP
- Heurisitcs
- Close the gap in approximation?
- PTAS for planar graphs?
- FPT algorithm?
- Greedy algorithm for DkS problem (bounded degree graphs)
- Algorithms for massive graphs?
