This talk is dedicated to the memory of my friend and colleague Chris Floudas

China, 2013

## UF FIORIDA

## Decomposition Techniques

## General

$>$ Decomposition techniques for solving optimization problems have been used as early as in the 1960's for linear mixed integer and convex optimization
$>$ Well known techniques include:

- Dantzig-Wolfe
- Benders
$>$ The choice of the decomposition (of objective function) influences the choice of the algorithm used to solve the corresponding optimization problem

## UF FLORIDA

## Decomposition Techniques

## Overview

$>$ Separable optimization:

$$
\begin{gathered}
\min _{x \in \mathbb{R}^{n}} F_{0}(x) \\
\text { s.t. } F_{i}(x) \leq b_{i}, i=1, \ldots, m \\
l_{i} \leq x_{i} \leq u_{i}, i=1, \ldots, m \\
\text { where each } F_{i}(x)=\sum_{j=1}^{n} F_{i j}\left(x_{j}\right), i=0,1, \ldots, m
\end{gathered}
$$

$>$ Factorable optimization:
See book:
Garth, McCormick, "Nonlinear Programming: Algorithms and Applications", 1983

## UF FIORIDA

## Decomposition Techniques

## Overview

$>$ Almost Block Separable Optimization:

$$
\min _{x \in \mathbb{R}^{n}} f(x)=f_{1}(u, y)+f_{2}(v, y)
$$

where $x=(u, v, y) \in \mathbb{R}^{n}$
and $u \in \mathbb{R}^{n_{1}}, v \in \mathbb{R}^{n_{2}}, y \in \mathbb{R}^{n_{3}}, n_{1}+n_{2}+n_{3}=n$
$y$ are called complicated variables [usually $n_{1}, n_{2} \gg n_{3}$ ]
$>$ Let $\varphi_{1}(y)=\min _{u} f_{1}(u, y), \varphi_{2}(y)=\min _{v} f_{2}(v, y)$
Then the above problem is equivalent to:

$$
\min _{y} \varphi_{1}(y)+\varphi_{2}(y)
$$

Note that if $f_{1}, f_{2}$ are convex, then $\varphi_{1}(y)$ and $\varphi_{2}(y)$ are convex

## UF

## DC Optimization Problems

## Overview

$>$ Many powerful techniques in global optimization are based on the fact that many objective functions can be expressed as the difference of two convex functions (so called d.c. functions)
$>$ If $D(x)$ is an objective function in $\mathbb{R}^{n}$, then the representation $D(x)=p(x)-q(x)$, where $p, q$ are convex function is said to be a d.c. decomposition of $D$
$>$ The space of d.c. functions is closed under many operations frequently encountered in optimization (i.e., sum, product, max, min, etc)
$>$ Hartman 1959: Every locally d.c. function is d.c.
$>$ For simplicity of notation, consider the d.c. program:

$$
\begin{gathered}
\min f(x)-g(x) \\
\text { s.t. } x \in D
\end{gathered}
$$

where $D$ is a polytope in $\mathbb{R}^{n}$ with nonempty interior and $f$ and $g$ are convex functions on $\mathbb{R}^{n}$

## DC Optimization Problems

## Overview

$>$ By introducing an additional variable $t$, the above problem can be converted into the equivalent problem of Global Concave Minimization:

$$
\begin{gathered}
\min t-g(x) \\
\text { s.t. } x \in D, f(x)-t \leq 0
\end{gathered}
$$

with concave objective function $t-g(x)$ and convex feasible set $\left\{(x, t) \in \mathbb{R}^{n+1}: x \in D, f(x)-t \leq 0\right\}$.
$>$ If $\left(x^{*}, t^{*}\right)$ is an optimal solution of the above program then $x^{*}$ is an optimal solution of the initial d.c. program and $t^{*}=f\left(x^{*}\right)$
$>$ Therefore, any D.C. program can be solved by an algorithm for minimizing a concave function over a convex set.

## UF INTOLIDA

## Continuous DC programming

$>\mathrm{DC}$ function:
A real-valued function $f: \mathbb{R}^{n} \rightarrow \mathbb{R} \cup\{+\infty,-\infty\}$ s.t.

$$
f(x)=g(x)-h(x), \forall x \in \mathbb{R}^{n}
$$

where $g: \mathbb{R}^{n} \rightarrow \mathbb{R} \cup\{+\infty\}$ and $h: \mathbb{R}^{n} \rightarrow \mathbb{R} \cup\{+\infty\}$ are convex functions
$>$ DC program:
A program of the form:

$$
\begin{aligned}
& \min f_{0}(x) \\
& \text { s.t. } f_{i}(x) \leq 0, i=1,2, \ldots, n
\end{aligned}
$$

where $f_{i}(x)$ are convex functions $(i=0,1,2, \ldots, n)$

- It is equivalent to the unconstrained DC program:

$$
\inf _{x \in \mathbb{R}^{n}} f(x)=g(x)-h(x)
$$

## UF INLOSIDA

## Continuous DC programming

$>$ Subgradients:
A vector $x^{*}$ is a subgradient of a convex function $h$ at a point $x$ if:

$$
h(z) \geq h(x)+\left\langle x^{*}, z-x\right\rangle
$$

- The subdifferential of $h(x)$ is the set of all subgradients
> Conjugate functions:
A conjugate function $h^{*}: \mathbb{R}^{n} \rightarrow \mathbb{R} \cup\{+\infty\}$ of a convex function $h: \mathbb{R}^{n} \rightarrow \mathbb{R} \cup\{+\infty\}$ is :

$$
h^{*}(p):=\sup _{y \in \mathbb{R}^{n}}\{\langle y, x\rangle-h(x)\}
$$

- The conjugate function $h^{*}(y)$ of a function $h(x)$ is convex
- If $h(x)$ is a closed proper convex function, then $h^{* *}=h$
- Given closed convex functions $g, h: \mathbb{R}^{n} \rightarrow \mathbb{R} \cup\{+\infty\}$, it is:

$$
\inf _{x \in \mathbb{R}^{n}}\{g(x)-h(x)\}=\inf _{p \in \mathbb{R}^{n}}\left\{h^{*}(p)-g^{*}(p)\right\}
$$

## UF FIORIDA Continuous DC programming

$>$ DC Algorithm:

- Step 0 Find an inintial solution $x^{0} \in \operatorname{dom}_{R}(g)$. Set $t:=0$.
- Step 1 Find $p^{(t)} \in \partial_{R} h\left(x^{(t)}\right)$.
- Step 2 Find $x^{(t+1)} \in \partial_{R} g^{*}\left(p^{(t)}\right)$, where $g^{*}$ is the conjugate of $g$.
- Step 3 If $f\left(x^{(t+1)}\right)=f\left(x^{(t)}\right)$, stop. Otherwise, set $t:=t+1$, go to Step 1.
where $x^{(t+1)}=\arg \min _{y \in \mathbb{R}^{n}}\left\{g(y)-h\left(x^{t}\right)-\left\langle p, y-x^{(t)}\right\rangle\right\}$

## Continuous relaxations for discrete

 DC programming$>$ The positive support of $x \in \mathbb{Z}^{n}$ is:

$$
\operatorname{supp}^{+}(x):=\left\{i \in\{1,2, \ldots, n\}: x_{i}>0\right\}
$$

$>$ The indicator vector $\chi_{S}$ is defined by:

$$
\chi_{S}(i)=\left\{\begin{array}{l}
1, i \in S \\
0, i \notin S
\end{array}\right.
$$

$>$ There are two common discrete functions:
$>M^{\natural}$-convex functions:

- For all $x, y \in \mathbb{Z}^{n}$ and $i \in \operatorname{supp}^{+}(x-y)$, function $h: \mathbb{Z}^{n} \rightarrow \mathbb{Z} \cup$ $\{+\infty\}$ is $M^{\natural}$-convex if it satisfies:

$$
\begin{gathered}
h(x)+h(y) \geq \min \left\{h\left(x-\chi_{i}\right)+h\left(x+\chi_{i}\right)\right\} \\
\min _{j \in \text { supp }^{+}(x-y)}\left\{h\left(x-\chi_{i}+\chi_{i}\right)+h\left(y+\chi_{i}-\chi_{j}\right)\right\}
\end{gathered}
$$

$>L^{\text {घ }}$-convex functions:

- For all $x, y \in \mathbb{Z}^{n}$, function $h: \mathbb{Z}^{n} \rightarrow \mathbb{Z} \cup\{+\infty\}$ is $L^{\natural}$-convex if it satisfies:

$$
h(x)+h(y) \geq h\left(\left\lceil\frac{x+y}{2}\right\rceil\right)+h\left(\left[\frac{x+y}{2}\right\rceil\right)
$$

## Continuous relaxations for discrete DC programming

$>$ Given two functions $g, h: \mathbb{Z}^{n} \rightarrow \mathbb{R} \cup\{+\infty\}$,

- The effective domain of $g$ is $\operatorname{dom}_{Z} g:=\left\{x \in \mathbb{Z}^{n}: g(x)<+\infty\right\}$
- The convex closure $\bar{g}(x): \mathbb{R}^{n} \rightarrow \mathbb{R} \cup\{+\infty\}$ of $g$ is: $\bar{g}(x)=\sup \left\{s(x): s\right.$ is an affine function, $\left.s(y) \leq g(y)\left(y \in \mathbb{Z}^{n}\right)\right\}$
- A convex extension $\hat{g}: \mathbb{R}^{n} \rightarrow \mathbb{R} \cup\{+\infty\}$ of $g$ is a convex function with the same function value on $x \in \mathbb{Z}^{n}$
- Let $\tilde{f}(x):=\bar{g}(x)-\hat{h}(x)$. Then $\tilde{f}(x):=g(x)-h(x), \forall x \in$ $\mathbb{Z}^{n}$. Thus:

$$
\inf _{x \in \mathbb{Z}^{n}} g(x)-h(x)=\inf _{x \in \mathbb{Z}^{n}} \tilde{f}(x) \geq \inf _{x \in \mathbb{R}^{n}} \tilde{f}(x)
$$

$>$ For convex extensible functions $g, h: \mathbb{Z}^{n} \rightarrow \mathbb{R} \cup\{+\infty\}$ with $\operatorname{dom}_{z} g$ bounded and $\operatorname{dom}_{z} g \subseteq d o m_{Z} h$, it is:

$$
\inf _{z \in \mathbb{Z}^{n}}\{g(z)-h(z)\}=\inf _{x \in \mathbb{R}^{n}}\{\bar{g}(x)-\hat{h}(x)\}
$$

where $\bar{g}(x)$ is the linear closure of $g(x)$ and $\hat{h}(x)$ is any convex extension of $h(x)$

## UF Fivinilia DI Optimization Problems

$>$ Monotonicity with respect to some variables (partial monotonicity) or to all variables (total monotonicity) is a natural property exhibited by many problems encountered in applications. The most general problem of d.i. monotonic optimization is:

$$
\begin{gathered}
\min f(x)-g(x) \\
\text { s.t. } f_{i}(x)-g_{i}(x) \leq 0, i=1, \ldots, m
\end{gathered}
$$

where all functions are increasing in $\mathbb{R}_{+}^{n}$
$>$ Assume without loss of generality that $g(x)=0$
$>\left\{\forall i f_{i}(x)-g_{i}(x) \leq 0\right\} \Leftrightarrow \max _{1 \leq i \leq m}\left\{f_{i}(x)-g_{i}(x)\right\} \leq 0 \Leftrightarrow F(x)-$ $G(x) \leq 0$, where:

$$
F(x)=\max _{i}\left\{f_{i}(x)+\sum_{i \neq j} g_{j}(x)\right\}, G(x)=\sum_{i} g_{i}(x)
$$

$>F(x)$ and $G(x)$ are both increasing functions

## UF HFORIDA DI Optimization Problems

$>$ Problem reduces to:

$$
\begin{gathered}
\min f(x) \\
\text { s.t. } F(x)+t \leq F(b) \\
G(x)+t \geq F(b) \\
0 \leq t \leq F(b)-F(0) \\
x \in[0, b] \subset \mathbb{R}_{+}^{n}
\end{gathered}
$$

$>$ A set $G \subseteq \mathbb{R}_{+}^{n}$ is normal if for any two points $x, x^{\prime}$ such that $x^{\prime} \leq x$, if $x \in G$, then $x^{\prime} \in G$
$>$ Numerous global optimization problems can be reformulated as monotonic optimization problems. Such problems include multiplicative programming, nonconvex quadratic programming, polynomial programming and Lipschitz optimization problems

## Decomposition and Multi-objective Optimization

## Overview

$>$ Consider the following problems:

$$
\begin{align*}
\min _{x \in D \subseteq R^{n}} F(x) & =f_{1}(x)+\cdots+f_{m}(x)  \tag{1}\\
\min _{x \in D \subseteq R^{n}} f(x) & =\left(f_{1}(x), \ldots, f_{m}(x)\right) \tag{2}
\end{align*}
$$

[2] is a multi-objective optimization problem
Let $E(f, D) \subseteq D$ be the set of all Pareto optimal solutions in $D$
$>$ Theorem: If $\bar{x}$ is an optimal solution of problem [1], then $\bar{x} \in E(f, D)$ of problem [2]
$>$ Theorem: Let $h_{i}(t)$ be monotonic increasing functions for $i=1, \ldots, m$. Consider the multi-objective optimization problem

$$
\begin{equation*}
\min _{x \in D \subseteq R^{n}} h(x)=\left(h_{1}\left(f_{1}(x)\right), \ldots, h_{m}\left(f_{m}(x)\right)\right) \tag{3}
\end{equation*}
$$

Then $E(f, D)=E(h, D)$.

## UF FIORIDA Kolmogorov's Superposition

## Overview

$>$ Theorem: For any integer $n \geq 2$ there are continuous real functions $\psi^{p, q}(x)$ on the closed unit interval $E^{1}=[0,1]$ such that each continuous real functions $f\left(x_{1}, \ldots, x_{n}\right)$ on the $n$-dimensional unit cube $E^{n}$ is representable as

$$
f\left(x_{1}, \ldots, x_{n}\right)=\sum_{q=1}^{2 n+1} \chi_{q}\left[\sum_{p=1}^{n} \psi^{p q}\left(x_{p}\right)\right]
$$

where $\chi_{q}(y)$ are continuous real functions
$>$ For $n=3$, by setting:

$$
\begin{gathered}
\varphi_{q}\left(x_{1}, x_{2}\right)=\psi^{1 q}\left(x_{1}\right)+\psi^{2 q}\left(x_{2}\right) \\
h_{q}\left(y, x_{3}\right)=\chi_{q}\left[y+\psi^{3 q}\left(x_{3}\right)\right]
\end{gathered}
$$

we obtain from the above:

$$
f\left(x_{1}, x_{2}, x_{3}\right)=\sum_{q=1}^{7} h_{q}\left[\varphi_{q}\left(x_{1}, x_{2}\right), x_{3}\right]
$$

## MAX-DFSS Problem

$>$ An undirected connected graph $G=(V, E)$ with at least $k+1$ vertices is $k$-vertex-connected if it remains connected whenever fewer than $k$ vertices are removed
$>$ The problem of finding a minimum weight $k$-vertex-connected subgraph is NP-hard when $k \geq 2$
$>$ The minimal $k$-connected spanning subgraph problem is considered instead
$>$ Boros et al considered how to generate all minimal $k$-vertexconnected spanning subgraphs in incremental polynomial time
$>$ We consider a routing system characterized by a minimal 2-vertex-connected spanning subgraph with some high-degree vertices.

- We name it the degree-concentrated maximum faulttolerant spanning subgraph problem (MAX-DFSS)
- Finding a maximum weight of minimal 2-vertex-connected spanning subgraph is also hard to solve

## UF INLORIDA

## MAX-DFSS Problem

## Formulation

$>$ Given an undirected graph $G=(V, E)$, we need to find a minimal 2 -connected spanning subgraph. The aim is to maximize the sum of the squares of the degree of each vertex:

$$
\max \sum_{v \in V} \operatorname{deg}_{S}(v)^{2}
$$

s.t. $S$ : minimal 2-connected spanning subgraph
$>$ This problem is the fault tolerant version of the problem of fault tolerant version for the degree-concentrated spanning tree problem (DST) of (Maehara et al, 2015)
$>$ It can be applied in spanning tree routing system (Tanenbaum, 2010).
$>$ In (Maehara et al, 2015), the monitoring of network communications is considered

## UF FORIDA MAX-DFSS Problem <br> Algorithms

$>$ Greedy algorithm for the MAX-DFSS problem:

- Input. 2-connected graph $G=(V, E)$
- Output. A minimal 2-connected spanning subgraph $S \subseteq G$
- Step $1 S \leftarrow G$
- Step 2 Repeat

Step 2.1 If $S$ is minimal 2-connected, go to step 3.
Step 2.2 Select an edge e ${ }^{*} \in$

$$
\underset{\substack{e \in E(S) \\ \text { is } 2-\text { connected }}}{\arg \max } \sum_{v \in V(S-e)} \operatorname{deg}_{S-e}(v)^{2}
$$

Step $2.3 S \leftarrow S-e^{*}$

- Step 3 Output $S$

## MAX-DFSS Problem

## DC Formulation

$>$ Now we formulate the problem as a DC program.
Let $M \in \mathbb{R}^{|V| \times|E|}$ be the incidence matrix for graph $G$.
$>$ Let $x_{e} \in\{0,1\}, \forall e \in E$ indicate whether edge $e$ is chosen into the subgraph or not.
For any $x \in\{0,1\}^{|E|}$ we obtain a subgraph $S=\left\{e \in E: x_{e}=1\right\}$

$$
M x=\left(\operatorname{deg}_{s}\left(v_{1}\right), \operatorname{deg}_{s}\left(v_{2}\right), \ldots, \operatorname{deg}_{s}\left(v_{n}\right)\right)^{T}
$$

$>$ The objective function $\sum_{v \in V} \operatorname{deg}_{S}(v)^{2}$ can be formulated as $x^{T} A x$, where $A=M^{T} M \in \mathbb{R}^{|E| \times|E|}$. $A$ is positive semi-definite.
$>$ The problem becomes:

$$
\max x^{T} A x
$$

s.t. $\left\{e \in E: x_{e}=1\right\}$ is a minimal 2-connected spanning subgraph
$>$ If $g(x)=\left\{\begin{array}{r}0,\left\{e \in E: x_{e}=1\right\} \text { is a minimal 2-connected spanning subgraph } \\ +\infty, \text { otherwise }\end{array}\right.$ the problem is equivalent to $\min _{x \in\{0,1\}^{n}} g(x)-x^{T} A x$

## UF FORIDA MAX-DFSS Problem <br> DC Algorithm

$>$ DC algorithm for the MAX-DFSS problem:

- Step 0 Choose $x^{(0)} \in \operatorname{dom}_{R}(g)$ to be an initial solution. Set $t:=0$
- Step 1 Compute $p^{(t)} \in \partial h\left(x^{(t)}\right)$
- Step 2 Compute $x^{(t+1)} \in \partial g^{*}\left(p^{(t)}\right)$, i.e.,,,

$$
x^{(t+1)}=\arg \min _{y}\left\{g(y)-\left\langle p^{(t)}, y\right\rangle\right\}
$$

- Step 3 If $f\left(x^{(t+1)}\right)=f\left(x^{(t)}\right)$, go to Step 4. Otherwise, set $t:=t+1$, go to Step 1
- Step 4 Call Greedy algorithm for the MAX-DFSS on the graph represented by $x^{(t)}$.

## MAX-DFSS Problem

## Complexity Evaluation

$>x^{(t+1)}$ can be obtained by solving a maximum weighted minimal 2connected spanning subgraph with edge weight $p_{e}^{(t)}$ for $e \in E$
$>$ Instead, we can find a 2-connected subgraph with at most $2|V|-2$ edges and the total weight is at least 0.5 times the maximum total weight of minimal 2 -connected spanning subgraph.
$>$ Lemma: Suppose $S^{*}$ is a maximum weight minimal 2-connected spanning subgraph of $G$ and $T^{*}$ is a maximum weight spanning tree of $S^{*}$. Then $p\left(T^{*}\right) \geq p\left(S^{*}\right) / 2$.
$>$ Therefore, the complexity of the following algorithm is $O\left(|V|^{3}\right)$

## MAX-DFSS Problem

## Algorithms

$>$ Algorithm for the MAX-DFSS problem:

- Input 2-connected graph $G=(V, E, p)$ where $p$ is the edge weight vector
- Output 2-connected spanning subgraph $S \subseteq G$ with at most $2|V|$ edges
- Step 1 Find out a maximum spanning tree $T$ of $G$ by Prim algorithm
- Step $2 S \leftarrow T$
- Step 3 Repeat

Step 3.1 Perform block decomposition for S. If it has only one block, go to step 4.
Step 3.2 Search the maximal weighted edge $e \in E \backslash$ S striding over different blocks
Step 3.3 $S \leftarrow S+e$

- Step 4 Output S

## UF FIORIDA MAX-DFSS Problem <br> Computational results

$>$ Computational results can be found in:

Solving the degree-concentrated fault-tolerant spanning subgraph problem by DC programming Chenchen Wu, Yishui Wang, Panos M. Pardalos, Dachuan Xu, Zhao Zhang, Ding-Zhu Du (submitted, 2017)
