Annotation

In this work we improve the speed of the nearest neighbor classifiers of a set of points based on sequential analysis of high-dimensional feature vectors. Each input object is associated with a sequence of principal component scores of aggregated features extracted by deep neural network. The number of components in each element of this sequence is dynamically chosen based on explained proportion of total variance for the training set. We propose to process the next element with higher explained variance only if the decision for the current element is unreliable. This reliability is estimated by matching of the ratio of the minimum distance and all other distances with a certain threshold. Experimental study for face recognition with the Labeled Faces in the Wild and YouTube Faces datasets demonstrates the decrease of running time up to 10 times when compared to conventional instancebased learning

Proposed approach

The task of set-of-points classification is formulated as follows. It is required to assign an input set of T feature vectors x(t) = [x1(t),...,xD(t)] into one of C classes. They are specified by a training set of R≥C points xr = [xr1,...,xrD], $r \in \{1,...,R\}$, which class label $c(r) \in \{1,...,C\}$ is known. We assume that dimensionality D is rather high, e.g., when deep convolutional neural network (CNN) is used for feature extraction

Classification algorithm

The proposal is to consider L hierarchical levels of image representation so that at the l-th level of the hierarchy (l = 1, 2, ..., L) only d_l principal components are compared. The number of features (d_l) at each hierarchical level is determined according to a fixed rate of explained variance σ_l of the learning set. Since σ_1 < $\sigma_2 < \cdots < \sigma_L = 1$, $d_l = D$

The distance between feature level to speed-up the matching

$$\rho\left(\widetilde{x}^{(l)},\widetilde{x}_{r}^{(l)}\right) = \rho\left(\widetilde{x}^{(l-1)},\widetilde{x}_{r}^{(l-1)}\right) + \sum_{d_{l-1}+1}^{d_{l}} \rho(\overline{x}_{d},\overline{x}_{r,d})$$

Nearest neighbor class

 $c_l^* = \underset{c \in C_l}{argmin} \rho_c(\widetilde{x}^l)$

The set of candidates

$$C_{l+1} = \left\{ c \in C_l \left| \frac{\rho_c(\widetilde{x}^l)}{\rho_{c_l^*}(\widetilde{x}^l)} \le \delta \right\} \right\}$$

Aggregation techniques

1. Average features vectors

 $\overline{x} = \frac{1}{T} \sum_{t=1}^{T} x(t)$ $x^* = \underset{x(t)}{\operatorname{argmin}} \sum_{t'=1}^{\infty} \rho(x(t), x(t'))$

2. Medoids

3. Median features

 $x' = [x'_1, \dots, x'_D]$

Experimental data

Convolutional neural networks

Datasets

Lightened CNN (Version C) - 256 elements

YouTube Faces (YTF): 1595 people 3425 videos 48-6070 frames

VggFace2 – 2048 elements VggFace – 4096 elements

FaceNet – 512 elements

Labeled Faces in the Wild (LFW): 1680 people 13000 facial photos

IAPRA Janus Benchmark (IJB-C): 31334 facial photos of 3531 people 117542 frames of 11779 videos

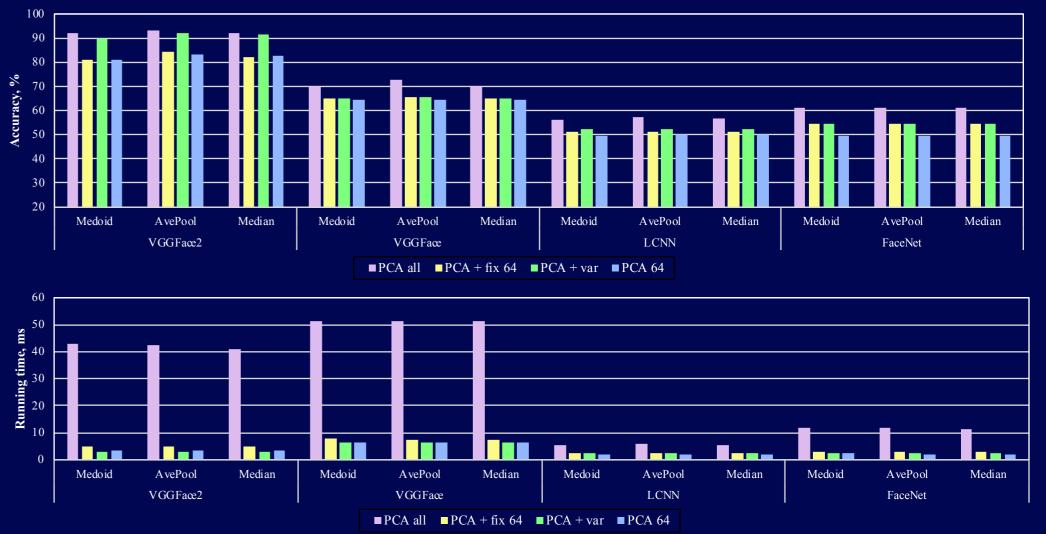

Experimental results

The performance of the k-NN classifier in face recognition, LFW dataset:

Metric	Classifier	VGGFace	LCNN	VGGFace2	FaceNet
Accuracy (%)	k-NN, all components	96.31	97.48	98.66	98.15
	k-NN, 64 components	94.10	96.21	96.95	97.36
	sequential k-NN, fixed number of components	95.97	96.97	98.32	98.15
	sequential k-NN, the number of components is determined by the explained variance	95.80	96.81	97.98	97.94
Time (ms)	k-NN, all components	50.39	4.88	34.78	9.37
	k-NN, 64 components	2.53	2.50	2.53	2.52
	sequential k-NN, fixed number of components	2.92	2.54	2.84	2.69
	sequential k-NN, the number of components is determined by the explained variance	3.20	2.23	2.81	1.87

Here the proposed approach is only 0.3-1% less accurate when compared to the traditional k-NN for all features, though 2-10-times speed-up is obtained. Conventional matching of only fixed number of principal components is 0.6-1.7% less accurate than the proposed implementation of sequential analysis

The dependencies of recognition accuracy and running time on various aggregation techniques for LFW(train) - YTF(test):

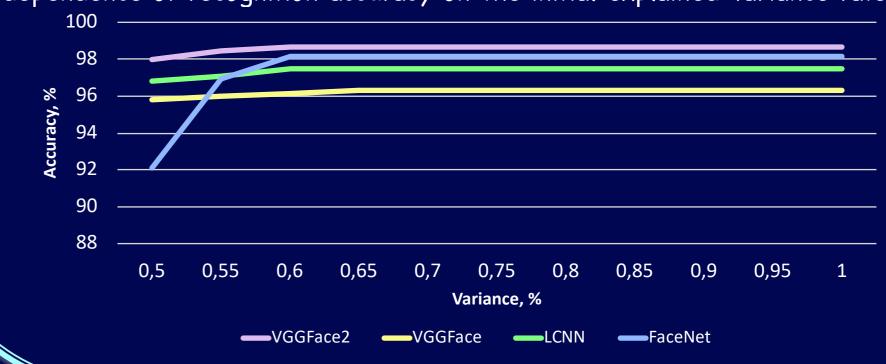

The most effective results were demonstrated by PCA with variable number of components in each level obtained by increasing explained variance for features extracted by VGGFace2 CNN

The performance of the k-NN classifier in face recognition, IJB-C dataset:

Metric	Classifier	VGGFace2	FaceNet
Accuracy (%)	k-NN, all components	98.66	98.15
	k-NN, 64 components	96.95	97.36
	sequential k-NN, fixed number of components	98.32	98.15
	sequential k-NN, the number of components is determined by the explained variance	97.98	97.94
	k-NN, all components	34.78	9.37
Time	k-NN, 64 components	2.53	2.52
(ms)	sequential k-NN, fixed number of components	2.84	2.69
	sequential k-NN, the number of components is determined by the explained variance	2.81	1.87

The dependence of recognition accuracy on the initial explained-variance rate:

Conclusion

In this work we proposed the modification of the k-NN classification method based on sequential analysis of high-dimensional features. Experiments with face recognition and contemporary deep features demonstrated that our approach is up to 8-10-times faster when compared to the original k-NN method, while the accuracy decreases only by 0.1-0.9\%. The main direction for further research is to examine sophisticated classifiers in order to increase the recognition accuracy. Moreover, it is important to use more difficult dissimilarity measures, e.g., implement metric learning to point-to-set and set-to-set distance learning
